(54) Viscous product dispenser having externally located, dispensed product shearing outlet valve provided with lost-motion action

(57) The actuating lever 48 of the dispenser has an outlet valve flap 64 integral therewith which moves in a shearing action across the outlet of the discharge spout 38 as the actuator is returned to its standby position such that the returning valve flap cleanly slices through the bead of viscous product adhering to the spout and thus fully separates, the dispensed bead of product from that remaining behind in the spout. A lost-motion action permits the valve flap to uncover the spout outlet before ends 58 of actuator legs 52 contact body surface 60 and further depression of the actuating lever shifts the pumping piston 32 through its dispensing stroke to force product out the spout. The dispenser includes a spring 44 to return the piston 32 to its starting position after each dispensing stroke, and a follower piston 20 takes up the reduction in volume of the product.

·n nn 21572724

SPECIFICATION .

Viscous product dispenser having externally located dispensed product shearing outlet 5 valve provided with lost-motion action

Technical Field

This invention relates to the field of manuallyoperated pumping dispensers having particu-10 lar utility for viscous products such as toothpaste and the like.

Background

In co-pending application Serial Number 15 06/565,540, filed December 27, 1983, and assigned to the assignee herein, a viscous product dispenser is disclosed showing an actuating lever provided with an integral, external valve that opens and closes the dis-20 charge outlet of the spout. That arrangement has proved to be very attractive in many respects, particularly where the function of a checking outlet valve is desired that will not interfere with or disrupt the laminar flow of 25 product from the dispenser during the pumping stroke, e.g., where the product being dispensed comprises toothpaste having layers of striping substance carefully laminated therein and whose integrity must be main-30 tained for aesthetic reasons in the bead of product which is dispensed from the unit.

It has been found, however, that the "trapdoor-like" movement of the prior valve during
closing tends to cause a quantity of the product to be pressed against the spout and
create an unsightly residue. This also tends to
cause the dispensed product bead to adhere
to the valve and not fully separate from the
product remaining within the spout. Addition40 ally, it has been found that in some cases
product is attempted to be pumped out of the
spout by the moving pumping piston before
such time as the valve flap has adequately
uncovered the outlet.

Summary of the Present Invention

Accordingly, an important object of the present invention is to improve upon the outlet valve and actuator construction disclosed in said prior application in such a way that the benefits of such prior construction are retained, yet the problems associated with improper cut off of the dispensed product and unsightliness at the discharge spout are eliminated, as well as premature pumping action.

Pursuant to the foregoing, the present invention contemplates constructing and arranging the valve flap and extremity of the spout such that the flap moves across the outlet in a guillotinelike shearing action as the flap returns to its closed position. In this respect the valve flap moves through an arcuate path of travel having an axis which coincides with the axis of the arcuate surface at the extremity of the spout, such that the valve flap can move

in close, contiguous relationship with the end of the spout during its return movement to cleanly sever the dangling product bead from the spout without in any way striking the 70 spout or otherwise being impeded in its freedom of movement in this respect. Furthermore, the combination actuator and outlet valve unit is mounted on the discharge spout in such a way that the unit has an initial 75 degree of lost motion, sufficient to at least substantially uncover the spout outlet, before such time as further continued depression of the actuator portion of the unit causes the pumping piston to commence its movement 80 through a pumping stroke. Consequently, the valve flap is well removed from the spout outlet as the product begins to emanate from the outlet under the influence of the pumping 85

Brief Description of the Drawings

Figure 1 is a vertical cross-sectional view of a dispenser constructed in accordance with the principles of the present invention and showing the actuator thereof in its undepressed, standby position with the spout outlet fully closed by the valve flap portion of the actuator;

Fig. 2 is a fragmentary vertical cross-sec-95 tional view of the dispenser as in Fig. 1 but showing the actuator at the completion of its initial lost-motion travel during which time the valve flap portion of the actuator has uncovered the spout outlet but depression of the. 100 pumping piston has not yet commenced; and

Fig. 3 is a fragmentary vertical crosssectional view of the dispenser similar to Fig. 2 but showing the actuator operated to its fullest extent wherein the pumping piston is fully 105 depressed.

Detailed Description

The dispenser 10 includes a tubular, cylindrical body 12 which is open at its lower end 110 14 to the atmosphere via an aperture 16 in a decorative closure panel 18 or the like which spans the lower end 14. A floating piston 20 makes sealing engagement with the interior wall surface of the body 12 and has a down-115 wardly and outwardly flaring metal skirt 22 or the like on the bottom thereof which likewise engages the interior surface of body 12. The skirt 22 is sufficiently resilient that it will deflect downwardly to any extent necessary to permit the piston 20 to rise in the body 12 yet is at the same time sufficiently stiff as to bite into the wall surface during attempted, downward movement of the piston 20 within body 12, thereby preventing such retrograde 125 movement.

The opposite end 24 of the body 12 includes an upright, centrally disposed sleeve 26 supported by transversely extending web means 28. The sleeve 26 reciprocably re130 ceives the tubular stem 30 of a pumping

45

piston 32 which at its circumferential periphery sealingly engages the inner wall surface of the body 12. A passage 34 is defined within the tubular stem 30, and the two pistons 20 and 32 cooperate with the body 12 to form a pumping chamber 36 there-

The sleeve 26 also partially receives the lower end of a tubular discharge spout 38 10 which itself receives the upper end of the plunger stem 30 and is securely attached thereto. A passage 40 is defined within the spout 38, and a discharge outlet 42 is presented at the uppermost end thereof. A coil 15 spring 44 encircles the piston stem 30 and is trapped between the lower extremity of the spout 38 and a lower, in-turned terminus 46 of the sleeve 26 for the purpose of yieldably biasing the piston 32 and the spout 38 to-20 ward an upper, undepressed position as illustrated in Fig. 1.

The dispenser 10 is also provided with an actuator unit broadly denoted by the numeral 48 pivotally mounted on a fulcrum 50 on the 25 spout 38. The fulcrum 50 takes the form of a pair of pins projecting laterally from opposite sides of the spout 38, and a pair of legs 52 of the actuator unit 48 (only one leg 52 being illustrated) straddle the spout 38 and rest at 30 their midpoints upon the respective fulcrum

pins 50. The legs 52 project forwardly at such an angle and to such an extent that they underlie respective ledges 54 on the body 12 adjacent 35 the spout 38. Each of such ledges 54 has a first bottom surface 56 at the outermost extremity thereof which abuttingly engages the opposite side of the proximal leg 52 from the corresponding fulcrum pin 50 when the actu-40 ator 48 is in the standby position of Fig. 1, thus cooperating with the fulcrum pins 50 to trap the leg 52 therebetween. Spring pressure from the spring 44 assists in this regard, and the geometry is such that the actuator 48 45 tends to remain up in its Fig. 1 position with

the legs 52 projecting downwardly and forwardly so that their outermost ends 58 are spaced below a second bottom surface 60 on each of the ledges 54 spaced inwardly from 50 the terminal edge surface 56 thereof.

The actuator 48 includes a finger-engaging portion 62 on one side of the fulcrum pins 50 and a valve flap portion 64 on the opposite side thereof. The flap portion 64 is integrally 55 joined with the finger-engaging portion 62 by an intermediate web portion 66, the valve flap portion 64 being of such dimension as to completely cover and thus close the outlet 42 when the actuator 48 is in its Fig. 1 position.

The outermost surface extremity of the spout 38 at the outlet 42 is transversely arcuate, having a center or axis coinciding with the fulcrum pins 50. Likewise, the valve flap 64 itself, particularly the underside 65 thereof, is transversely arcuate in complemen-

tal relationship with the arcuate surface of the outlet 42. Thus, the exposed surface of the outlet 42, the undersurface of the valve flap 64, and the axis of pivoting movement of the 70 actuator unit 48 all have centers or axes which coincide with one another at the fulcrum pins 50. Preferably, the valve flap 64 is so positioned that its undersurface lightly contacts the outwardly facing surface of the outlet 75 42 when the actuator 48 is in its Fig. 1

position.

If desired, the dispenser 10 may be provided with an overcap 68 which snaps down on to the body 12 via interfitting snap beads 80 70 at the base of the overcap 68. A transverse top wall 72 of the overcap 68 may be disposed to abuttingly engage the upper rear extermity of the valve flap 64 when the latter is in a position fully closing the outlet 85 42 as illustrated in Fig. 1 for the purpose of supplementing the force of the spring 44 tending to keep the valve flap 64 in a closed position.

90 Operation

The return spring 44 normally maintains the pumping piston 32, the spout 38, and the actuator unit 48 in the position of Fig. 1 in which the valve flap 64 tightly covers, closes off, and thus seals the outlet 42. After removal of the overcap 68, application of downwardly directed finger pressure to the fingerengaging portion 62 of the actuator 48 will cause the latter to rock downwardly about the 100 fulcrum pins 50 in a clockwise direction, sliding the valve flap 64 off the outlet 42 in the same direction until the condition as illustrated in Fig. 2 is reached. During such initial

lost-motion movement, the upper edge sur-105 faces 56 of the ledge 54 remain in engagement with the corresponding legs 58, and the point of contact of the legs 58 with such surfaces 56 is moved slightly along the legs 52 toward the outer ends 58 thereof. There is 110 also a very slight, miniscule amount of downward movement of the spout 38 during this

timeframe since the distance between the fulcrum pins 50 and the surfaces 56 of ledges 54 is increased slightly at this time to permit 115 the outermost ends of the legs 52 to swing upwardly into abutting engagement with the second surfaces 60 of the ledges 54.

As it will be clearly seen in Fig. 2, by the time the outer ends 58 of the legs 52 have swung up to and engaged the second surfaces 60, the outlet 42 is substantially entirely opened by the valve flap 64. Yet, no substantial pumping motion of the pumping piston 32 has occurred.

As depression of the finger-engaging por-125 tion 62 then continues, the outer ends 58 of the legs 52 fulcrum against the surfaces 60 as the actuator unit 48 changes its fulcrum point from the pins 50 to the points of 130 engagement of the legs 52 with surfaces 60

21572724 1 5

of ledges 54. During such time, the pumping piston 32 becomes depressed and the legs 52 move away from the first surfaces 56 until the condition of Fig. 3 is reached, at which time a 5 full pumping stroke has been completed in one direction.

Thereafter, releasing finger pressure on the portion 62 allows the spring 44 to raise the pumping piston 32 and the spout 38 back 10 toward the Fig. 1 position thereof, while at the same time rotating the actuator 48 in a counterclockwise direction. By the time the actuator 48 reaches the position illustrated in Fig. 2, the valve flap 64 will just begin to 15 slide back over the outlet 42. At this time there will be a sufficient amount of spring movement left in the spring 44 to continue to urge the actuator 48 counterclockwise in a lost-motion action as the piston 32 substan-20 tially comes to a halt.

As the valve flap 64 then slides downwardly across the open end of the outlet 42, it slices through the bead of product extending from the spout 34 and severs the same in 25 the nature of a quillotine from the product left behind. By the time valve flap 64 is fully returned into covering relationship with the outlet 42, the bead of product has been completely disconnected from that remaining 30 within the spout 38 in a neat, clean, and visually pleasing manner, leaving no clinging unsightly residue of any consequence in and around the outlet 42.

In view of the evacuation of product within 35 the chamber 36 and the closing of the outlet 42 by valve flap 64, the floating piston 20 is moved upwardly within the chamber 36 by a corresponding amount as atmospheric pressure is applied against the bottom of the 40 piston 20 via the aperture 16 in the aesthetic end cover 18. In this respect, it will be appreciated that, depending on the nature of the product being dispensed, the valve flap 64 serves in the capacity of a check valve to 45 prevent significant retrograde movement of product back through the spout 38 in an effort to replenish that portion of the chamber 36 which has been evacuated during the immediately preceding pumping stroke. Con-50 sequently, the piston 20 is enabled to float upwardly within the chamber 36 in the proper manner to decrease the effective volume of the chamber 36 by the amount of discharged

product. It will be appreciated that only a single embodiment of the present invention has been disclosed herein. However, various obvious modifications to the disclosed embodiment will be apparent to those skilled in the 60 art without departing from the spirit and underlying principles of this invention. Thus, the scope of the present invention should be deemed to include any such obvious modifications as may from time to time be made by 65 those skilled in the art.

CLAIMS -

 In a dispenser for viscous products having an outlet at the end of a product dis-70 charge passage and controlled by an external valve which opens and closes the outlet, the improvement comprising:

means mounting the valve for transverse shearing movement of the latter across the 75 outlet during return of the valve to a position closing said outlet whereby to promote severance of a dispensed bead of product from that

remaining in the discharge passage.

2. In a dispenser as claimed in Claim 1, 80 wherein said valve and said outlet have complementally configured, transversely arcuate surfaces which are disposed in mutually confronting relationship when the valve is closed, said mourning means including structure 85 adapting the valve for arcuate movement about an axis which is at least substantially coincident with the axis of curvature of said

In a dispenser as claimed in Claim 1, 90 wherein said valve is coupled with a manually engageable actuator for operating the valve, said actuator being coupled with means for discharging product from said outlet when the actuator is operated.

In a dispenser as claimed in Claim 3, wherein said actuator is coupled with said discharging means in such a way that said valve is at least substantially uncovered from the outlet by the actuator before product is 100 attempted to be discharged by said discharg-

ing means. 5. In a dispenser as claimed in Claim 4, wherein said valve and said actuator comprise integrally molded portions of a common unit 105 having leg means projecting therefrom, said discharging means being movable by the actuator and including a fulcrum pin means engaged by said leg means intermediate the opposite ends thereof, said dispenser having a 110 first stationary surface in spaced opposition to said fulcrum pin means and cooperating with the latter in pivotally capturing said leg means therebetween during initial lost-motion movement of the actuator to open said valve, said 115 dispenser further having a second surface spaced from said fulcrum pin means and disposed for fulcruming engagement with the

outer end of said leg means during continued movement of the actuator following said lost-120 motion opening of the valve as the leg means

is rocked away from said first surface. 6. A dispenser for viscous products com-

a generally tubular body provided with a 125 discharge spout at one end thereof;

> a pumping piston disposed within the body and secured to said spout for reciprocal movement of the spout and the piston together relative to the body during pumping strokes, said piston being tubular and cooperating

130

with the spout to define a discharge passage for product from the interior of the body;

a take-up piston initially disposed at the opposite end of the body and movable within the latter only in a direction toward the pumping piston for progressively advancing the mass of product within the body toward the pumping piston following each discharge of product;

a combination actuator and outlet valve unit pivotally mounted on said spout externally of

the latter.

25

said unit being initially pivotal by the manual movement of an actuator portion thereof 15 through a lost-motion segment of travel from a first position in which a valve portion of the unit closes the outlet of the spout to a second position in which said valve portion at least substantially uncovers the outlet without signi-20 ficant operation of said pumping piston, and thence being further pivotal by said actuator portion to a third position by which the pumping piston is operated to force product from the body; and

means operably associated with said unit for yieldably biasing the same toward said first position and said pumping piston to an

unoperated dispostion.

7. A dispenser as claimed in Claim 6, 30 wherein said valve portion of the unit is disposed for shearing movement across said outlet during lost-motion return of the unit from said second position to said first position, whereby to promote effective severance 35 of a dishcarged bead of the product from that product remaining behind in the spout.

A dispenser as claimed in Claim 7, wherein said unit has a leg projecting therefrom, said spout having a fulcrum pin pivo-40 tally engaged by said leg intermediate the opposite ends thereof, said container having a first stationary surface in spaced opposition to said fulcrum pin and cooperating with the latter to pivotally capture said leg there-45 between during initial lost-motion movement of the unit to open said valve portion, said container further having a second surface spaced from said fulcrum pin and disposed for fulcruming engagement with the outer end of 50 said leg during continued movement of the unit following said lost-motion opening of the valve portion as the leg is rocked away from said first surface.

CLAIMS

Amendments to the claims have been filed, and have the following effect:

Claims 1-8 above have been deleted or 60 textually amended.

New or textually amended claims have been filed as follows:

 A dispenser for viscous products, comprising an outlet at the end of a product 65 discharge passage, an external valve for open-

ing and closing the outlet, and means mounting the valve for transverse shearing movement of the latter across the outlet during return of the valve to a position closing said 70 outlet whereby to promote severance of a dispensed bead of product from that remaining in the discharge passage.

A dispenser according to claim 1 wherein the valve is coupled with a manually engageable actuator for operating the valve, the actuator being coupled with means for discharging product from the outlet when the

actuator is operated.

A dispenser according to claim 2, 80 wherein the actuator is coupled with the discharging means in such a way that the valve is at least substantially uncovered from the outlet by the actuator before product is attempted to be discharged by the discharging 85 means.

A dispenser according to claim 3, whereby the actuator is movable from a first position in which the valve closes the outlet to a second position in which the valve at least-90 substantially uncovers the outlet without significant operation of the discharging means and thence to a third position in which the discharging means is operated to discharge product from the outlet.

5. A dispenser according to claim 1, 95 wherein the valve and the outlet have complementally configured, transversely arcuate surfaces which are disposed in mutually confronting relationship when the valve is closed, the 100 mounting means pivotally mounting the valve for arcuate movement about an axis which is at least substantially coincident with the axis of curvature of said surfaces.

6. A dispenser according to claim 5, com-105 prising a manually engageable actuator forming with the valve a common unit, a generally tubular body provided with a discharge spout at one end thereof, a pumping piston disposed within the body and secured to the

110 spout for reciprocal movement of the spout and the piston together relative to the body during pumping strokes, the piston being tubular and co-operating with the spout to define the discharge passage for product from

115 the interior of the body to the outlet at the end of the spout, and the pivotal mounting means comprising leg means projecting from the unit fulcrum pin means as the spout engaged by the leg means intermediate the

120 opposite ends thereof, a first stationary surface on the body in spaced opposition to the fulcrum pin means and co-operation with the latter pivotally to capture the leg means therebetween during initial movement of the actua-

125 tor to open the valve, and a second stationary surface on the body spaced from the fulcrum pin means and disposed for fulcruming engagement with the outer end of the leg means during continued movement of the actuator

130 following the initial movement as the leg

21573724 1 -

means is rocked away from the first surface and the spout and the piston are moved relative to the body, a take-up piston initially disposed at the opposite end of the body and movable within the latter only in a direction towards the pumping piston for progressingly advancing the means of product within the body towards the pumping piston following each discharge of product, and means operatoly associated with the unit for yieldably biasing the latter towards closure of the valve.

7. A dispenser for viscous products, substantially as hereinbefore described with reference to the accompanying drawings.
